What is a Debris Flow?

**Debris Flow Definition**

A debris flow is a moving mass of loose mud, sand, soil, rock, water and air that travels down a slope under the influence of gravity. To be considered a debris flow, the moving material must be loose and capable of “flow,” and at least 50% of the material must be sand-sized particles or larger. Debris flows often occur in an area recently burned by wildfire.

Some debris flows are very fast—these are the ones that attract attention. In areas of very steep slopes they can reach speeds of over 100 miles per hour, though most travel between 10 and 30 miles per hour.

How do debris flows happen in California?

California is susceptible to large wildfires (A) that can occur during warm, dry, windy conditions. Following wildfires, the soil and denuded hillsides (B), for a period of several years, can become water repellant (C). When it rains, if heavy enough, can result in flash flooding and debris flows in areas recently burned by wildfire (D). Debris flows generally are a result of high-intensity short-duration rainfall falling on the steeper slopes of a recently burned area and can occur at any time of the year. In fact, flash flooding and debris flows can occur outside of burned areas as well as a result of heavy rainfall.
Preparing for post wildfire debris flow risks

Residents and businesses need to prepare in advance for flood conditions. Before the threat of flooding becomes imminent, residents and business owners should:

- Purchase a flood insurance policy
- Review your current insurance policy and become familiar with what is covered and ensure the limits adequately protect their building and personal belongings.
- Make an emergency kit, plan evacuation routes, and keep important papers in a safe, waterproof place.
- Itemize and take pictures of possessions.

For more information regarding a policy, please call your insurance agent. You can also visit FloodSmart.gov or call 1-800-427-2419 to find a local agent.
